

ACAD Attribute

This is used to store information in your drawings

They are all user defined

When you have an item like you use today in your elements, but where the tag can be freely defined

Then I can confer DXF attributes on a correct way to element objects

This solves also the question of some people to have extra information into an element

The solution I see is I think simple to create an extra field in the XML structure of your existing field

Or create a second field called "User field" to define user dynamic values in the element editor

For direct use you only have to show the text value when drawing the element into a schema

Then with this extra field the tool of nuri can filter out the requested information for the user specific needs

```
<input
  text="_"           -> attribute value of acad
  size="9"
  x="10"
  y="25"
  tagg="user"       -> to make the difference with the existing one
  label="user label" -> attribute name of acad
  rotate="true"
/>
```
